# Chapter 1

## Introduction

The Conrad Observatory, a geophysical observatory, monitors the physical parameters of our planet. It is named after the Austrian geophysicist Victor Conrad (1876 - 1962), who for many years worked at the Zentralanstalt für Meteorologie und Geodynamik (ZAMG) in Vienna. The observatory is almost entirely underground and guarantees constant temperature for all applied techniques. With its range of supported measurement techniques, instrumentation and the layout of the underground facilities, the Conrad Observatory represents a unique research and development location for earth scientists of all disciplines. The Conrad Observatory includes two main facilities: (1) The seismo-gravimetric observatory (SGO), which was opened in 2002, and (2) the geomagnetic observatory (GMO), officially opened in 2014. The basic task for earth observatories is the observation of temporal and spatial variations of physically relevant parameters, which are crucial to our understanding of processes on earth. At the Conrad Observatory, earthquake activity (seismology), changes in gravity and mass distribution, geomagnetic field variations, geodetic parameters, atmospheric conditions and meteorological data are all continuously monitored.

This yearbook provides an overview of geomagnetic measurements performed at the Conrad Observatory. It also contains detailed descriptions of data treatment, analytical methods, quality assessment and results. Long- and short-term variations of the geomagnetic field, e.g. secular variation and geomagnetic activity, are analysed and discussed. The yearbook of the Conrad Observatory is published every year and made available online following the links provided on the title page. The electronic data from the Conrad Observatory can also be requested online at our data portal (<https://cobs.zamg.ac.at>)

## Chapter 2

# Location and Instrumentation

The geomagnetic part of the Conrad Observatory is located at Trafelberg, Lower Austria, about 50 km south-west of Vienna. Three different geological formations are found in the vicinity of the Conrad Observatory: the Gutenstein Formation, Reifling Formation, and Wetterstein Limestone. All of them are dominated by very weakly magnetic limestones and dolomites of predominantly Middle Triassic age (247.1 - 237 Ma) [Wessely, 2006]. The observatory is part of a large underground installation covering the full geophysical monitoring program including seismology, gravity, meteorology and geomagnetism. The geomagnetic section consists of a 1 km long tunnel system, which includes several adits dedicated to electric and magnetic measurement systems. A location map indicating the positions of various instruments described below is shown in Figure 2.1. Absolute determinations of earth magnetic field directions, also referred to as DI measurements, are conducted within the absolute area at the northern end of the main tunnel. The main azimuth mark is located at the southern end of the main tunnel in a distance of 380 m. A further azimuth mark is located northwards (not shown) on a mountain at a distance of  $\approx 2.5$  km.

The following instruments are deployed at the Observatory for magnetic measurements: 3 Fluxgate sensors, 6 Overhauser sensors, and several other magnetic sensors. Auxiliary temperature measurements have been performed at all Fluxgate sensor positions, at their electronics and at several other positions in the tunnel. As will be shown below, temperature variations and magnetic gradients are extremely small throughout the observatory. Details on instrumentation are provided in Table 2.1. The primary instruments used in determination of definitive data are printed in bold. Beside the above mentioned permanently running instruments, the Conrad Observatory additionally operates several DI Theodolite/Fluxgate combinations including an automated version (AutoDIF) for base value determination. There are several measurement systems for magnetic remanence measurements and rock magnetism as well as mobile sensors for field work and prospection. A three-dimensional Merritt coil system with an axis length of 3 m for sensor calibration tests complements the portfolio.

# Chapter 3

## Methods

### 3.1 Acquisition and data transmission

Variations in directional components of the Earth's magnetic field at the Conrad Observatory in 2021 are mainly based on measurements from a LEMI036 sensor. This instrument is installed in hdz orientation within the tunnel system of the geomagnetic observatory (Figure 2.1). It fully satisfies the current one-second INTERMAGNET minimum requirements. The LEMI036 vector magnetometer samples the magnetic field and its data is digitally filtered to 10 Hz. One-second and one-minute values are produced using the standard INTERMAGNET Gaussian filter [St-Louis, 2020]. A GP20S3 scalar magnetometer, which samples the field at 1 Hz, is used to determine the geomagnetic field intensity. As with vector measurements, filtered values are produced using a Gaussian filter. Most measurement systems at the Conrad Observatory are connected to a *Magpy Automated Realtime Acquisition System* (MARTAS) [Leonhardt et al., 2013], which reads e.g. serial communication data and buffers field records. Any data is then continuously streamed using MQTT (Message Queuing Telemetry Transport). A *Magpy Automated Realtime Collection and Organisation System* (MARCOS) subscribes to MARTAS clients and collects all data and the related metadata within a MySQL database. An independent analysis process frequently checks the contents of the database and produces all data products near realtime. Adjusted data sets are then forwarded on to our data portal and the INTERMAGNET gins every 5 minutes. GPS signals are used to ensure exact timestamps. As all measurements are performed underground, the GPS signal is transferred by optical fibres to the cabinets in the tunnel, which house the sensor electronics and the MARTAS. The time delay, conservatively estimated making use of the manufacturer's data as well as distance considerations between outside GPS antenna and cabinet, is about  $10^{-6}$  seconds. Each setup of sensor and acquisition unit is equipped with an independent lightning protection system and a local uninterruptible power supply facilitating approximately 72 hours of service after power loss. An observatory wide uninterruptible power supply with roughly 40 hours of power adds to this two-step protection system and primarily secures data transfer towards the two redundant MARCOS servers. Data acquisition is therefore safe for about 5 days in the case of a full power loss. Data acquisition as well as all analyses including filtering procedures, baseline calculations, format conversions, and others discussed here, are performed using MagPy packages [Leonhardt et al., 2016]. Version 1.0.6 is available at <https://github.com/geomagpy/magpy>.

## 3.2 Baseline adoption

Magnetic observatories record the geomagnetic field from very high frequencies, which is of particular interest for the study of externally triggered field variations such as pulsations and geomagnetic storms, up to long term variations covering months and years, which mainly have internal sources and are required to analyse secular variation over decades and centuries. However, vector magnetometers tend to drift over such long time scales, due in part to temperature variation, ageing of the device and slow pillar movements. The drift of the instruments deployed at the Conrad Observatory is rather small (less than 0.32 nT per year for 2021), nevertheless it is necessary to perform DI measurements, which precisely determine the declination and inclination using a fluxgate theodolite [*Jankowski and Sucksdorff*, 1996]. The vector value is then reconstructed by additionally using independent measurements of a scalar magnetometer. Their drift, which is usually assumed to be negligible, is tested by comparing independent records of several instruments.

For absolute measurements we use several different types of fluxgate theodolites. The primary instrument is a T010B 160391 07-2018 equipped with a MAG01H 504-0911H 03-2016 fluxgate magnetometer. In addition, we also perform frequent measurements with other fluxgate theodolites as listed in table 3.1. Most measurements are conducted on the absolute pier A2. The primary azimuth mark is 380 m away at the southern end of the tunnel, which ensures the absence of any thermal fluctuations when aiming. The primary, permanently recording F instrument, located on pier AS-O-40, is 100 m distant from the main absolute pier A2 and shows a total constant F difference of -1.6 nT. Magnetic field differences between all absolute piers are regularly measured by an additional scalar magnetometer, which is moved every week on another of the 16 piers. Table 3.2 summarizes all delta values within the absolute area of the Conrad Observatory. Overall the horizontal gradients within this area of the tunnel system at pier height are on average less than 0.13 nT/m (maximum: 0.42 nT/m), indicating perfect measurement conditions by international standards [*Jankowski and Sucksdorff*, 1996]. Since the opening of the observatory, absolute measurements have been made on average every 7.0 days, which is sufficient to monitor expected variation/drift signals at this location. Measurements make use of the 'residual' technique [*Lauridsen*, 1985]. DI values are measured, typed into an online form, automatically analysed using MagPy and stored within the observatory databases. It should be noted here that the analysis algorithm requires variation data in a magnetic coordinate system (HDZ, HEZ). Beside routine measurements on pier A2, automatic measurements are periodically performed on pier A16 using an AutoDIF system [*Rasson and Gonsette*, 2011]. Furthermore, DI measurements are conducted once a month in a wooden hut (pier H1) outside the tunnel approximately 350 m south-west of A2 using a mire perpendicular to the two main azimuth marks of A2 for stability control. These measurements are discussed below.

Table 3.2. Delta values for all piers with respect to A2. These delta values need to be added to data from the respective pier to correct the measurements towards A2.

Pier	Distance to A2 [m]	$\delta F$ [nT]	Epoch (F)	$\delta D$ [ArcSec]	$\delta I$ [ArcSec]	Epoch (Dir)
A1	1.75	-0.17	2021			
A10	4.38	-0.77	2021			
A11	7.38	-0.53	2021			
A12	7.47	-0.41	2021			
A13	2.38	-0.09	2021			
A14	2.65	0.26	2019

H1	353.89	1.08	2018	0.000	0.000	2021

### 3.3 Data analysis and products

Principally we publish and submit three types of data sets, which are distinguished by their information content and speed of availability: adjusted data, quasi-definitive data and definitive data. Adjusted data sets are produced and published completely automatically every 5 minutes. The following analysis steps are routinely performed every 5 minute cycle:

1. Filter incoming MQTT data streams from all instruments to one-second IAGA/INTERMAGNET recommended products.
2. Check availability of data and define primary instruments according to a priority list.
3. An automatic outlier detection tool (MagPy) is checking and flagging the one-second data product.
4. Get primary one-second variometer data, apply the flags, apply compensation fields, eventually transform towards HEZ.
5. Read all existing basevalues and calculate a constant baseline approximation using the geometric mean of the last three months.
6. Perform baseline correction with adopted constant baseline.
7. Get one-second scalar data, apply flags, apply latest pier offset.
8. Merge variation data and scalar data.
9. Store distribution formats (ImagCDF, IAGA-2000) and submit data to Edinburgh GIN.
10. Filter final data set to one-minute and repeat storage and submission.
11. Special analysis: k-value determination, storm detection, gradient analysis, web page plots.

As the baseline is very stable at the Conrad Observatory, the constant baseline approach is a fast and reasonable approximation of the definitive values (Figure 4.1). The automated outlier identification method uses relatively weak criteria. Therefore some outliers and artificial disturbances are still present in this data set.

Quasi-definitive data sets are produced in a semi-automatic routine. Once a week an automated job checks for current flagging information for the primary systems within the database. Whenever an observer has finished the flagging procedure by inspecting the data of the primary instruments for a certain time range, these dates are updated within the database. The QD job now extracts all yet unanalyzed data prior to the last inspected data minus one week. The additional week makes sure that basevalues are available as they are determined in a weekly period. Then basevalues are obtained and a one-year baseline is calculated using the latest baseline function parameters (see below). All other steps follow the procedure of adjusted data production.

Definitive data is produced once a year using a manual iterative process. In a first step, we review all existing flagging information for the respective year starting in December the year before until end of January, thus covering 14 month. For flagging we consider observatory notes and many additional sensors indicating traffic, environmental changes etc. We use difference analysis and gradients of individual instruments and analyse derivatives of signals. Any additional flag is added into the flagging database. Then we analyse one year of data using a constant baseline hypothesis (see next chapter for details). Step 1 definitive data is calculated and the overall delta values are examined. For step 2 we eventually add any additional flagging information. The baseline is now calculated using optimal functional parameters. Step 2 data is used to obtain and analyze pier differences. In the final step 3 we finally consider all pier differences and produce the final result. All analyses steps are performed on high-resolution data, usually with one-second intervals, for all sensors and combinations. One-minute definitive data is a filtered product of these results. Please note that for one-second data we do not fill gaps with data from other sensors as they might have different frequency characteristics. All final dissemination products (IAF, ImagCDF, IAGA-2000) are obtained from the final step 3 results. Further details are depicted in chapter 5.

$K$  values are calculated according to the FMI approach [Sucksdorff *et al.*, 1991], which is one of the IAGA recommended routines [Menvielle *et al.*, 1995]. The method uses three major steps: in the first run,  $K$  values are calculated by simply determining the maximum-minimum difference of the minute variation data within three hour segments. This is done for both horizontal components and the maximum difference is selected. Using a transformation table related to the Niemegek scale and a  $K9$  level of 500 nT, the  $K$  values are then calculated. Based on this step, a first estimate of the quiet daily variation ( $S_r$ ) is obtained. Finally, hourly means with extended time ranges (30min +  $m$  +  $n$ ) are obtained for each half hour.  $m$  refers to 120 minutes (0-3a.m., 21-24p.m.), 60 minutes (3-6, 18-21) or 0 minutes.  $n$  is determined by  $K^{3.3}$ . Using these newly obtained hourly means, the final  $K$  values are calculated. Preliminary data are made publicly available within 5 min on the ZAMG data distribution server and on the INTERMAGNET's website ([intermagnet.github.io](http://intermagnet.github.io)). Quasi-definitive data are produced following the methods described above and are usually provided within three weeks after acquisition on the same servers. Definitive data for each year are prepared within a couple of months after the end of the year. They can be retrieved from INTERMAGNET's website or from the website of the Conrad Observatory, Zentralanstalt fuer Meteorologie und Geodynamik (<http://www.conrad-observatory.at>). After a final cross-check by specialists from other institutions participating in INTERMAGNET, definitive data are published on a DVD/USB medium together with the definitive data from the whole INTERMAGNET network.

Earth observation data from the Conrad Observatory are licensed under CC Attribution (CC-

BY-NC-4.0). Publications making use of the data should include an acknowledgement statement of this form: The results presented rely on data collected at the Conrad Observatory, Austria. We thank the Zentralanstalt fuer Meteorologie und Geodynamik (ZAMG) for supporting its operation.

# Chapter 4

## Accuracy and Coverage

### 4.1 Basevalues and Baseline

#### 4.1.1 Primary baseline adoption

One measure of the accuracy of geomagnetic data is the quality of the baseline, i.e. the calibration curves that are used to correct the slow drift in time of the vector magnetometer in order to produce definitive data. Baselines for the Conrad Observatory are obtained for H (horizontal), D (declination) and Z (downward vertical) components by fitting a cubic spline curve to the correction values deduced from the absolute measurements. Each year the spline curve is calculated using data from mid-December of the previous year to mid-January of the following year in order to avoid discontinuities from one year to the next.

Base values and the corresponding best fitting baseline are shown in Figure 4.1. 139 absolute measurements by the WIC observers on pier A2 were considered for the analysis of 2021 (each one represented by a gray point). On average, DI measurements were performed with a period of 7 days. In a first run, a constant baseline approximation based on a median value of all basevalues is used. This approach is depicted by the blue line in Figure 4.1. Making use of this approximation and calculating the difference between this baseline corrected directional data and an independently recorded F value will result in a delta F value as shown in the blue curve in the lower plot of Figure 4.1. The here observed variation gives an indication about the actual complexity of the baseline. An optimal baseline was determined using MagPy's fitting function with a spline fit (knot parameter = 0.3, which is the normalized distance between spline knots) as shown by the red line in Figure 4.1. A more complex fitting function (e.g. magenta curve) does not improve the delta F value. For each component, a measure of quality of the absolute measurements was assessed by calculating the standard deviation of the residuals between all measurements and the baseline curve. The obtained standard deviations are 0.28 nT for H, 0.13 nT for Z and 4.8 arcsec for D, which are well within INTERMAGNET requirements. Calculated baseline curves have a maximum amplitude of 0.72 nT in the X and Z components, and 2.6 arcsec in the declination. Base values indicate a long term variation of the baseline with signal periods larger than half a year, therefore the typical frequency of one absolute measurement per week is sufficient to observe and correct these trends. Baseline variations are very limited throughout 2021. The resulting  $\delta F$  (see section 4.2) and variometer differences after baseline correction are virtually zero.

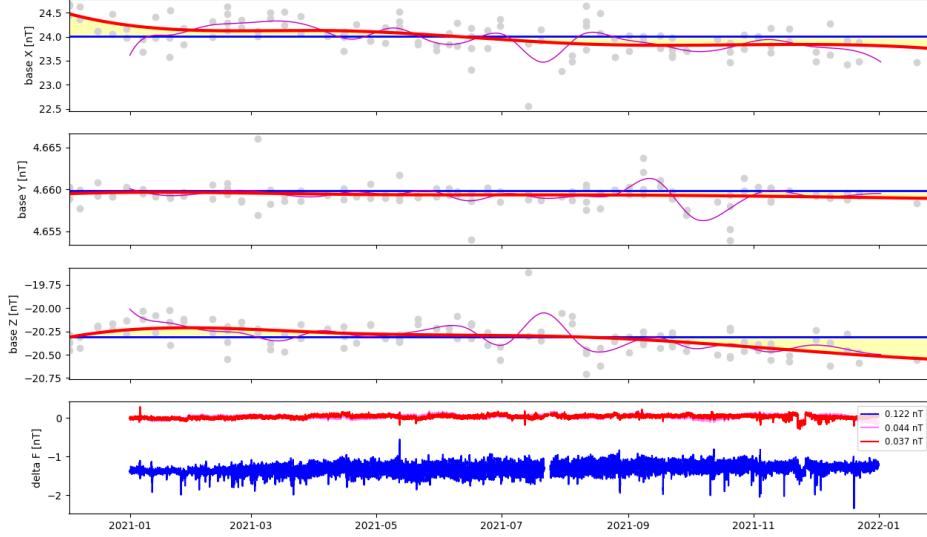

Figure 4.1 Basevalues for the primary vectorial system LEMI036 and iterative choice of optimal baseline. The first analysis step makes use of a constant baseline approximation (blue line). The resulting delta F values between baseline-corrected variometer and permanently recording F are depicted in the lower plot (also in blue) and show a considerable trend. According to this remaining trend a cubic spline fit (red) is chosen leading to a significantly improved delta F close to zero and characterized by a very low variance. Fitting small scale variations of basevalues (magenta) will not improve the delta F value. Actually the variance is getting larger again as expressed by the overall standard deviations given in the legend of the delta F plot. The red curve is therefore chosen as optimal baseline for definitive data.

#### 4.1.2 Consistency between measurement piers

Beside manual DI determination, an automatic DI measurement system (AutoDIF) [Rasson and Gonsette, 2011] is in operation at Conrad Observatory. The system is located on pier A16 (Figure 2.1). This automatic unit is configured to measure base values every 30 minutes. For analysis of this data, the site differences between A16 and the main pier A2, as listed in Table 3.2, are accounted for. As done for the manual measurements at pier A2 we also calculated the standard deviation of the residuals as a measure of quality. The obtained standard deviations are 0.62 nT for H, 0.30 nT for Z and 18.8 arcsec for D. A maximum amplitude of 2.60 nT in the X and Z components, and 161.0 arcsec in the declination is obtained. In 2021 DI measurements have been performed on six piers, A2, A4, A5, A7, A16, and H1. Beside the main pier A2, where most manual measurements were done, we do monthly manual determinations on piers A7, H1 and non-periodical measurements on A4, A5. Automatic AutoDIF measurements on pier A16 are performed every 30 minutes and are available except for February till April and a maintenance break in July. The clearly visible baseline jump is related to an insufficient laser beam initialization accuracy, resulting in a partial loss of azimuth measurement data and thus in wrong although consistent determinations. Therefore AutoDIF data has to be treated with

care in 2021. It is not used for our analysis. Figure 4.2 shows the average daily basevalues of all piers analysed for the main variometer. All basevalues are almost identical and exhibit a very similar almost linear trend which underlines the high quality and stability of the chosen adopted baseline shown as red line in Figure 4.2. Please note that for this plot the piers delta values as given in table 3.2 have been taken into account. In summary all tests support the high quality of the baseline of the Conrad Observatory.

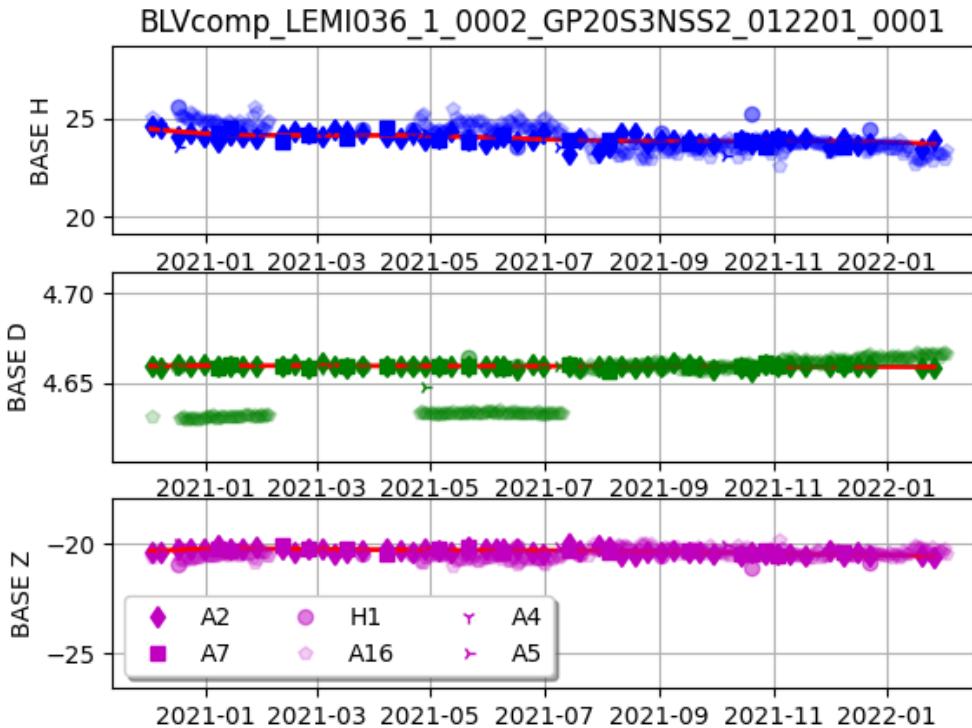

Figure 4.2 Combined plot of all basevalues for the LEMI036 variometer as determined on the piers given in the legend. Average pier differences as listed in Table 3.2 have been regarded for.

## 4.2 Delta F

The quality of the measurements can further be assessed by looking at the scalar residual, which is the difference between the field strength directly measured by a scalar magnetometer and the field strength derived from the vector measurement after drift correction with the baseline curve. As can be seen in Figure 4.3, the scalar residual of minute mean values corresponds to an average of 0.04 nT with a standard deviation of 0.04 nT. The maximum amplitude remains below 0.58 nT for the year 2021. Taking baseline and delta F uncertainty estimates into consideration by combining the scalar residual and statistical variation of absolute measurements results in a  $2\sigma$  uncertainty scenario with maximum values of  $\pm 0.32$  nT for all components in 2021. This is well within INTERMAGNET's requirement of a 5 nT accuracy for definitive data [St-Louis, 2020].

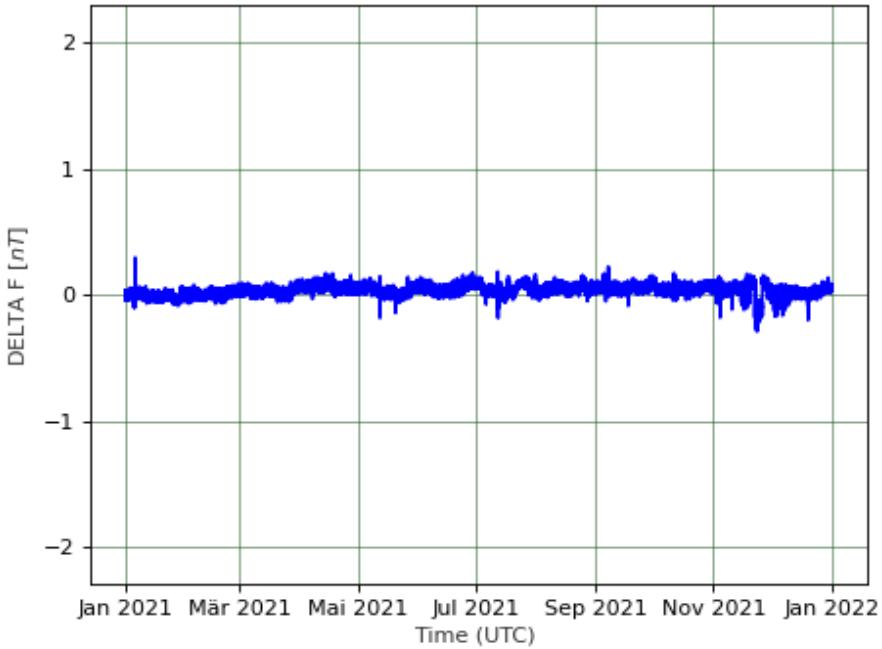

Figure 4.3 Delta F values between the scalar magnetometer and the field strength calculated from the baseline corrected vectorial data set. The scale of the figure is related to the INTERMAGNET 5 nT criteria.

### 4.3 Variometer differences

A third measure of quality comes from the comparison of records from different variometers after baseline correction. Additionally this test also provides an independent check of correctness of adopted baseline algorithms, especially if the two instruments are not identically oriented. For difference analysis, the orthogonal X, Y, and Z components of available variometer records after baseline correction are subtracted from each other. In 2021, variometer data from 2 independent systems are compared. In Figure 4.4, we depict these differences for each component and for each variometer relative to the primary variometer LEMI036. The scale of the figure is related to the INTERMAGNET 5 nT criteria, and the analysis makes use of filtered one-minute data. The average residual of the X component and its standard deviation is  $0.20 \pm 0.22$  nT. For the Y and Z component values of  $0.05 \pm 0.19$  nT and  $-0.09 \pm 0.12$  nT are obtained. Data from our secondary instrument is available from July 2021 onwards. Variation data of two instruments is available for 2021, full records from a LEMI036 and a LEMI025. All variometers are set up in HEZ orientation. Due to secular variation, the magnetic reference system changes with time and all systems slightly deviate from “perfect” orientation of Y towards magnetic east. These angular differences are considered in basevalue determination. After baseline adoption, the differences of all instruments is negligibly small, supporting the following three conclusions: 1) the algorithms and the calculation of adopted baselines, as depicted in section 3.2, are correct; 2) all instruments record an identical geomagnetic field at all periods; and 3) the combination of all accuracy tests

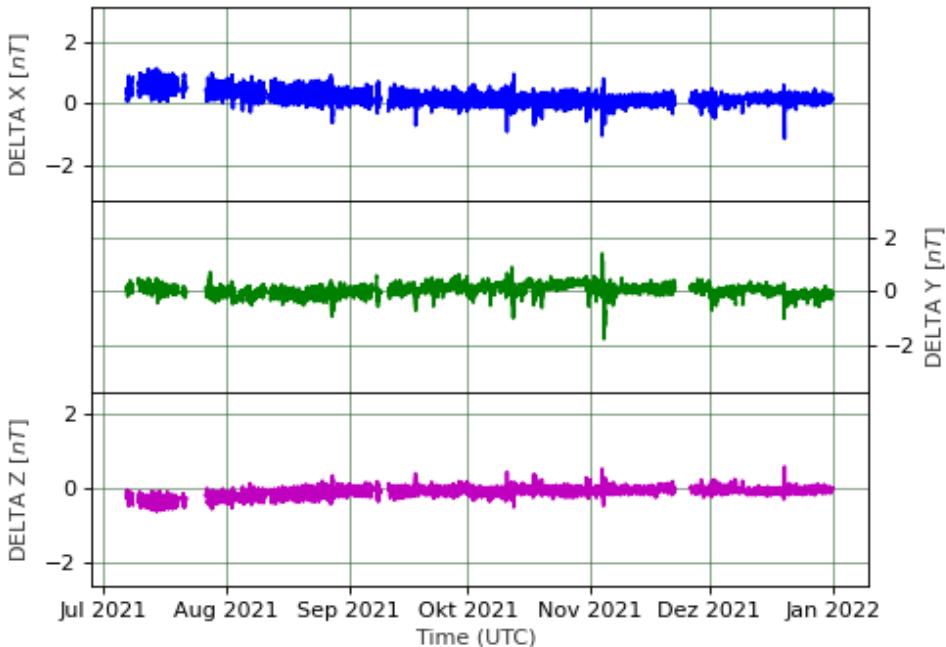

Figure 4.4 Delta values of vectorial components of baseline corrected variometer data.

underlines the very high quality of the geomagnetic field record.

#### 4.4 Residuals between absolute DI and definitive data

Another internal quality check makes use of absolute DI measurements, by calculating the residual between these absolute values and the definitive data product. If all analysis steps are valid and correct, the residual between DI and definitive data needs to be almost zero. For difference analysis both measurements are transferred into an XYZ coordinate system and subtracted from each other. Please note, that we are using the minute resolution definitive data here, requiring some interpolation. The average residuals are 0.010 nT for X, -0.012 nT for Y and 0.001 nT for Z underlying the correctness and quality of our analysis procedure and our final data products.

#### 4.5 Data coverage

A data coverage of 99.2 % of vectorial data in minute resolution was established for 2021. For filtering we use the recommended approach: minute means are only calculated if at least 90 % of one-second data is available within the filtering window. Therefore the relative recovery rate for one-second data is eventually higher. For scalar minute data, a data coverage of 100.0 % was obtained. One-second definitive data provided online consists solely of variation data from LEMI036 and scalar data from GP20S3NSS2 (see table 2.1). For minute data, gaps within the variation sequence were filled using secondary variometers. Gaps in the scalar one-minute record

are filled by data from secondary scalar systems. For 2021 the composite minute data set consists of contributions from all instruments shown in figure 4.5. Yellow shaded regions indicates the availability of variation data, green shaded regions indicate the presence of scalar data. The lowermost plot indicates average differences between all scalar values. The basic reason for only using single instrument records for our definitive one-second data is to maintain the frequency characteristics of the underlying instruments. For filtered one-minute data and longer periods, all instruments have widely similar characteristics within the frequency domain, which means an averaging and gap filling procedure is justified. Variation data is available almost continuously

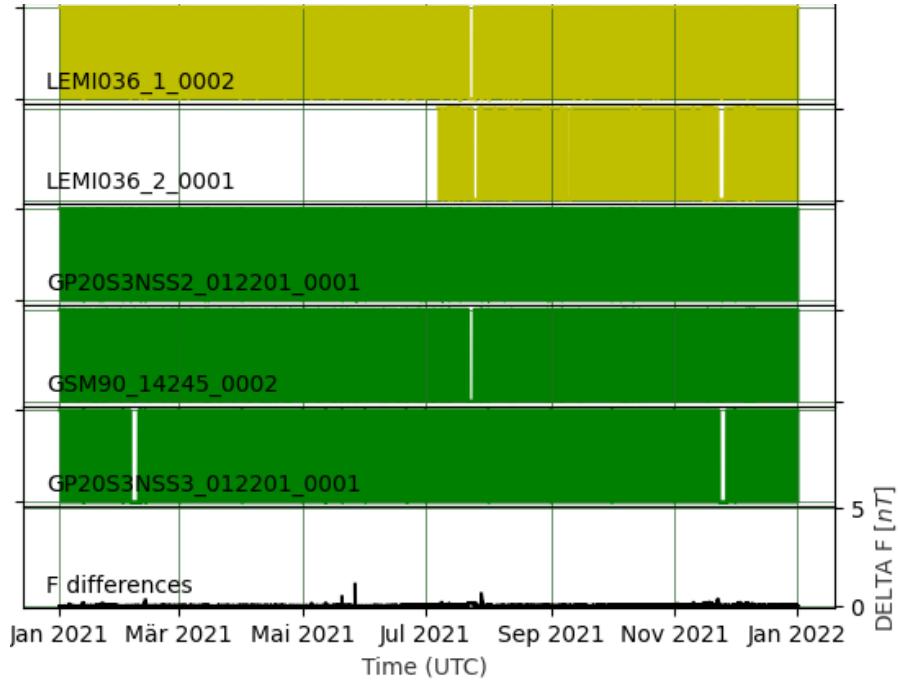

Figure 4.5 Contributions of each sensor for the analysis of 2021. Yellow shaded regions indicate time ranges of respective variometer data, green shaded regions mark scalar data which has been averaged for the composite one-minute record. The lowermost plot depicts the average difference between all scalar data.

for 2021. Minor gaps are mainly related to thunderstorms and disturbances due to wood work in the vicinity of the observatory. Gaps of the secondary variometer have been explained above. Thunderstorms occurred frequently and produced a lot of spikes. Table 8.2 in appendix gives an overview about days with thunderstorms and an estimate of independent lightning events with magnetic signatures. The one-second data record consists solely of data from LEMI036 SN1. For minute values, LEMI036 SN2 records merged into LEMI036 SN1 data to fill gaps, a procedure which is absolutely valid looking at the similarity of both records after baseline correction. Scalar data was mainly recorded with three instruments in 2021. One-second data is based solely on GP20S3NS2. For minute data, gaps are filled. Gaps in the scalar record have the same reasons as listed above for the variometer.

# Chapter 5

## Definitive Data

### 5.1 Definitive data production

A compilation of all results is shown in Figure 5.1. Vectorial components, after baseline correction, comprise the upper three plots. An independently measured value of the field strength  $F$  is shown below. Temperature variation is very small. The average temperature corresponds to  $6.21 \pm 0.02 \text{ }^{\circ}\text{C}$ . Please note that the absolute value of temperature is not accurately known; its variation, however, is very precise and almost negligible. The lower two plots show the locally determined  $K$  value and the global index  $K_p$  provided by the GFZ Potsdam, which have similar characteristics. All variometers located at the Conrad Observatory were set up in HEZ direction at the time of installation. Due to secular variation, the magnetic coordinate system is slowly moving in time. This will lead to increasing deviations from a perfect HEZ orientation for all variometers. The baseline correction technique of *Lauridsen* [1985], however, requires HEZ orientation. Even slight deviations from this boundary condition will lead to an improper variation correction which can result in slight offsets of  $\delta F$ , as an example. The LEMI036 variometer was set up in December 2015. Since then, the east component has moved by an angle of -0.988 degrees, which can be easily tested with reasonable accuracy by rotating the yearly average HEZ so that the average E component results in zero. For definitive data production, all calculations are performed on such coordinate-transformed data. A few magnetic events are visible in 2021 (Figure 5.1), marked by large vectorial deviations and high  $K$  indices. The events correspond to geomagnetic storms, in particular to coronal-mass ejections hitting earth. Throughout the year a gradual increase of  $Z$  and an increasing positive (east) declination is visible, as also found in the long-term trend in central Europa (see next chapter).

### 5.2 Comparison to preliminary and quasi-definitive data

Adjusted and quasi-definitive (QD) data is available from December 2015 onwards, although QD datasets are regularly uploaded to the GIN in Edinburgh only since end of 2018. Since then these data sets are primarily based on LEMI036 variation data as this instrument is widely undisturbed. Adjusted data show average absolute differences of less than 0.11 nT in x, less than 0.01 nT in y, less than 0.03 nT in z and less than 0.57 nT in  $F$ . Overall, the deviations from quasi-definitive data to definitive data is comparably small with average differences of less than 0.10 nT in x, less than 0.35 nT in y, less than 0.01 nT in z and less than 0.04 nT in  $F$ . The differences are well within the 5 nT range for suitable quasi-definitive data for both, our

adjusted and quasi-definitive data products.

## 5.3 Disturbances and anthropogenic signals

### 5.3.1 Frequency characteristics and noise levels

The spectral analysis of geomagnetic time series revealed some recurring magnetic disturbances. An average quiet day spectrum for definitive F of the GP20S3NSS2 potassium sensor is shown in Figure 5.2. Some small spectral peaks are visible at  $T = 300\text{s}$ ,  $\sim 220\text{s}$ ,  $\sim 180\text{s}$ ,  $\sim 150\text{s}$ ,  $\sim 130\text{s}$ ,  $\sim 120\text{s}$ ,  $\sim 110\text{s}$ ,  $T = 100\text{s}$ ,  $T = 70\text{s}$ ,  $50\text{s}$ ,  $35\text{s}$ ,  $\sim 7.5\text{s}$  and  $T = 5\text{s}$ . Also visible is a weak broadband distribution from  $300\text{s} < T < 3\text{s}$  and from  $10000\text{s} < T < 3\text{s}$ . The average noiselevel was found to be  $0.6^{pT}/\sqrt{\text{Hz}}$ . From the average spectrum the last  $l$  samples were used to dynamically derive the given noiselevel. This algorithm works as follows:

1. Set a percentage value  $r_x\%$  which defines the ratio of samples that will be used to derive the noiselevel. Typically 5% is a good value.
2. From the average spectrum derived by slepian tapering and FFTs find the index of the sample closest to the percentage value according to the following formula:

$$l = \min |r_x\% - [1/N, 1]_{\logspace}| \quad (5.1)$$

where  $[1/N, 1]_{\logspace}$  is a numerical row in logarithmic spacing from  $\log_{10}(1.0/N)$  up to 1 with  $N$  samples where  $N$  is the length of the onesided (positive) frequency series with length  $N$ .

3. Derive an incremental value  $Inc = l/100$ . If  $l < 100$  the derivation is not possible.
4. For all the samples in the interval from the shortest period up to the sample with index  $l$  append the maximum of the absolute value for each subinterval  $[k, k + Inc]$  to a list  $b$  for  $0 \leq k < l - 1$ .
5. Use the list of maximum absolute values per subinterval  $b$  to derive the noiselevel  $a_{noise}$

$$a_{noise} = \sqrt{\pi} \cdot \sqrt{\bar{b}^2} \quad (5.2)$$

where  $\bar{b}^2$  is the median of the squared  $b$  values.

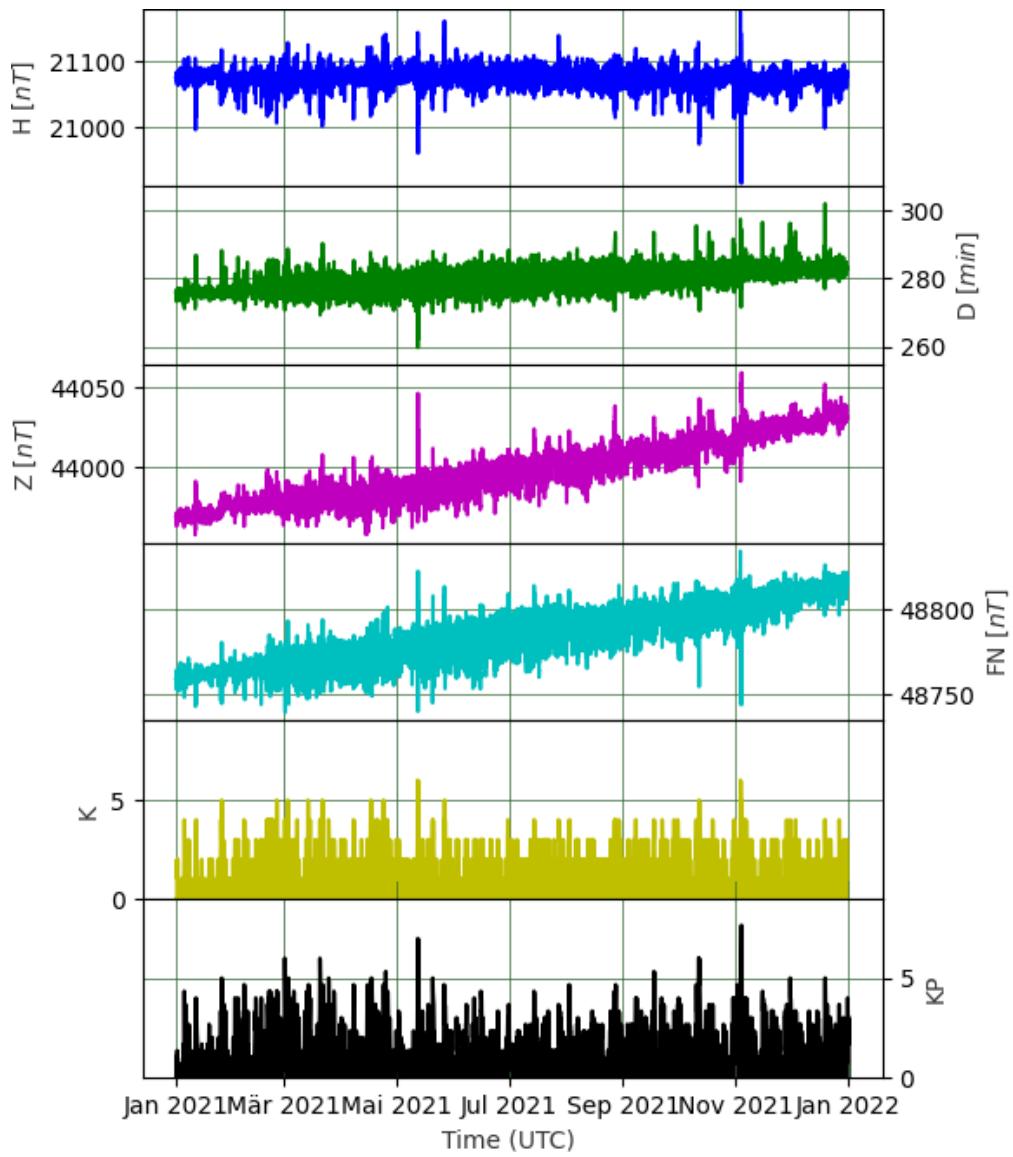

Figure 5.1 Definitive one-minute data of WIC. Shown are the three baseline corrected vectorial components, the independently determined F value, as well as local  $K$  and global  $K_p$  indices.

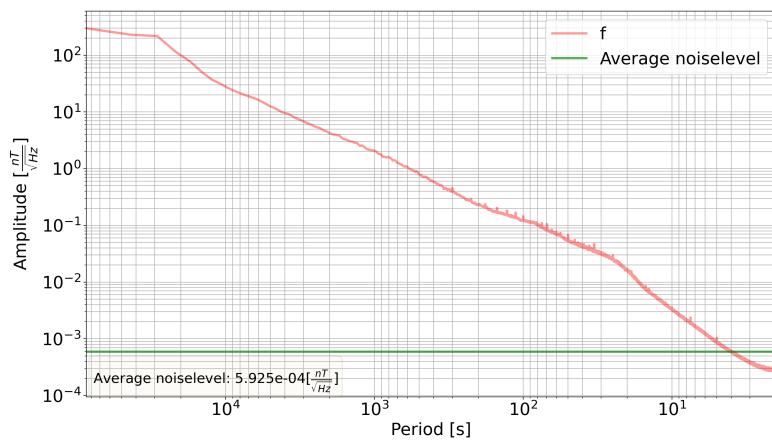

Figure 5.2 Average quiet day spectrum of total field intensity from definitive data of the GP20S3NSS2 potassium sensor.

# Chapter 6

## Geomagnetic Characteristics

### 6.1 Secular Variation

Geomagnetic secular variation originates in the dynamo processes of the Earth's outer core, where fluid flows generate the main magnetic field. In order to reduce geomagnetic contributions of external origin such as the interaction of the Sun's magnetic field with the Earth's magnetosphere, monthly and annual means are calculated. It should be mentioned that this procedure does not completely remove external field contributions. The monthly and yearly mean data for Conrad Observatory are provided in tables 6.1 and 6.2, respectively. After combining yearly means of the two Vienna observatories Cobenzl, WIK (running from 1955 to 2015), and the Conrad Observatory, WIC (from 2014 onwards), a secular variation diagram as shown in Figure 6.1 has been obtained. In the combination of both data sets, the Cobenzl annual means have been corrected towards the Conrad Observatory values using the average differences of years 2014 and 2015. Fortunately, the location difference ( $\approx 50$  km) and thus the averaged difference in each component is not large and constant in time between the two years of overlapping records (diff X =  $169 \pm 2$  nT, diff Y =  $-30 \pm 1$  nT, diff Z =  $-272 \pm 1$  nT).

As can be seen in Figure 6.1, field strength F and vertical component Z have been gradually increasing since 1955. The agonic, the line of zero declination, has been monotonously moving westwards and passed the Conrad Observatory in 1973. The H component has also increased since the beginning of observation, but has shown minimal variation since 1980. Considering the last two years, a secular variation rate of  $dX = -4.0$  nT/year,  $dY = 48.0$  nT/year and  $dZ = 62.0$  nT/year is obtained. Fitting and extrapolating an average annual derivative curve using cubic splines results in the following predicted average field values for 2022: H = 21070 nT, D = 4.79 deg, Z = 44063 nT. Please note that for this approximation it is assumed that the 50 km distant locations WIK and WIC have exhibited the same secular variation pattern in the past, as the WIK data has been corrected using constant offsets.

### 6.2 Geomagnetic Activity

#### 6.2.1 Local K values and $K_p$

The K-index ( $K$ ) and the planetary K-index ( $K_p$ ) are used to characterize the magnitude of geomagnetic activity.  $K_p$  is an excellent indicator of disturbances in the Earth's magnetic field and is used by many space weather prediction centres. Geomagnetic storms typically result in DC fluctuations in power grids, interruptions to spacecraft operations and GNSS due to

Table 6.1. Monthly arithmetic means at the Conrad Observatory. These mean values are deduced from minute data sets. If less than 90% of data is available then averages are not calculated.

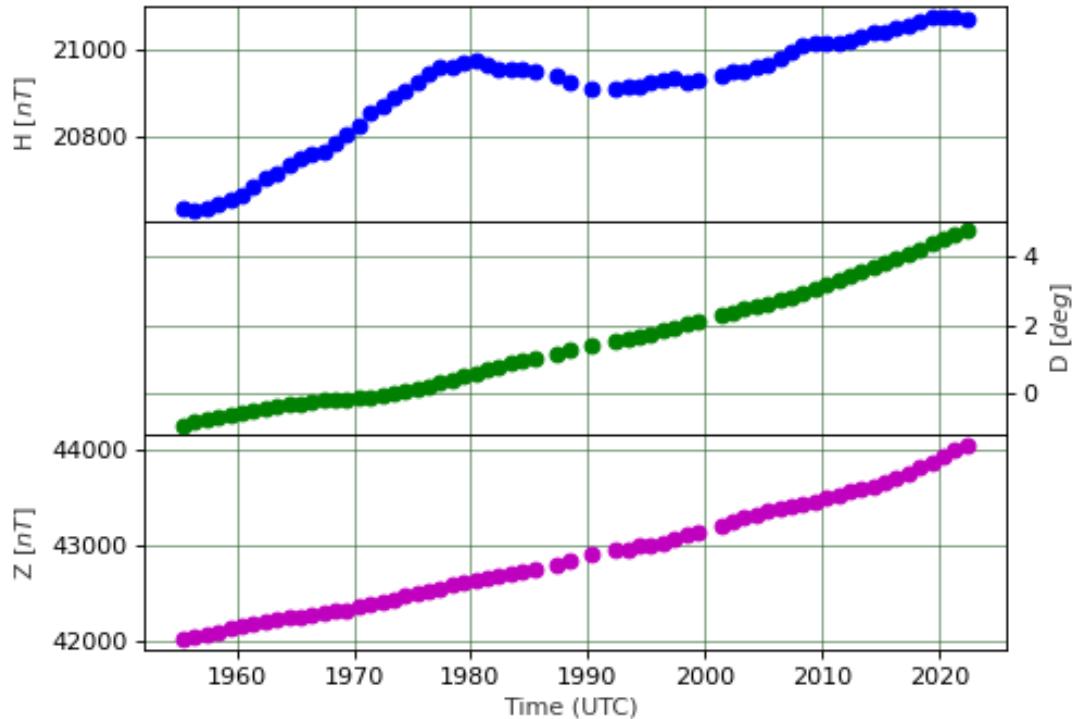

Figure 6.1 Yearly means since 1955. Data from 1955 until 2015 was obtained at the Cobenzl Observatory and corrected for the average offset of years 2014 and 2015 to the Conrad Observatory. Shown is also a predicted value for 2022.

ionospheric radio signal disturbances, and visible aurorae. The average local  $K$  for 2021 at Conrad Observatory corresponds to 1.5, which is in perfect agreement with the yearly average  $K_p$  of 1.5 provided by the GFZ Potsdam (<http://www.gfz-potsdam.de/kp-index/>). Figure 6.2 depicts the yearly and seasonal distribution of K values. As to be expected because of the orbital distance, the summer term is characterized by slightly higher average activity.

### 6.2.2 Quiet and disturbed days

On a global scale, quiet and disturbed days are identified based on three characteristics which each are used to define a single yearly or monthly ordering number (see <http://www.gfz-potsdam.de/sektion/erdmagnetfeld/daten-produkte-dienste/kp-index/erklaerung/qd-days/>). These parameters include (a) the sum of all  $K_p$  values of one day, (b) the sum of squares of all  $K_p$ , and (c) the maximum values of  $K_p$ . The three ordering numbers are then averaged and lowest and highest averages are selected. It has to be noted that this measure is purely relative and is not representative for classifying and comparing disturbance levels of different time periods. Therefore additional notes and codes are used based on the average daily  $A_p$  index, originating from eight  $a_p$  values which are the nT thresholds for

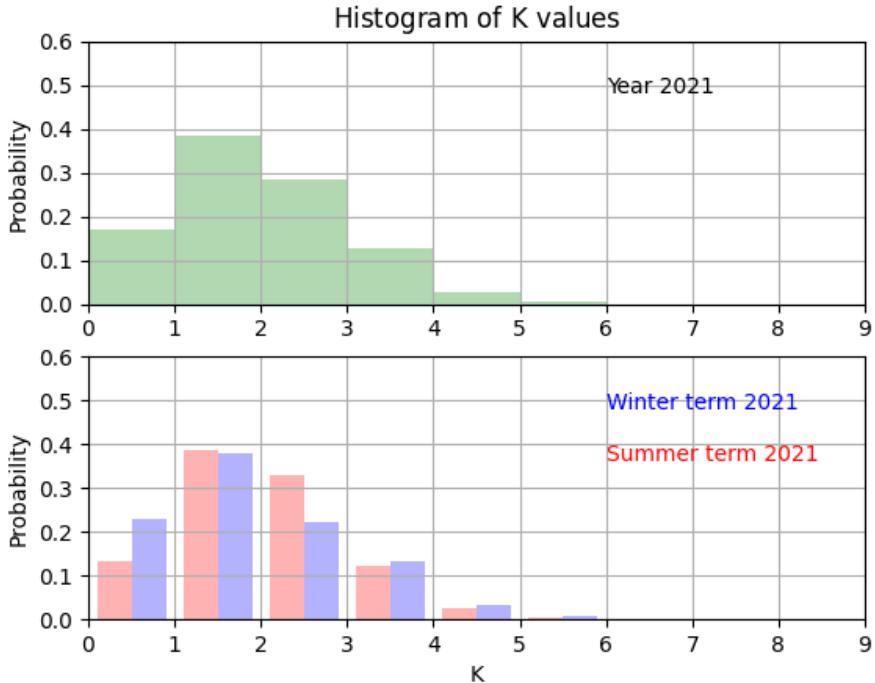

Figure 6.2 Distribution of K values.

each  $K_p$ . Detail can be found in the link above. For describing quiet and disturbed days at the Conrad Observatory, and to assure that data from all time periods is comparable, we prefer to use solely the average daily  $K$  index. Disturbed days are defined as days in which the average daily  $K$  index exceeds a value of 3.0. Such values were found for the following 9 days: 2021-03-01, 2021-03-14, 2021-03-21, 2021-04-17, 2021-05-12, 2021-05-27, 2021-10-12, 2021-11-04, 2021-11-06. For quiet days the average daily  $K$  index needs to be below 0.5, and this was found for 20 days: 2021-01-01, 2021-01-02, 2021-01-09, 2021-01-10, 2021-01-14, 2021-01-15, 2021-01-16, 2021-01-17, 2021-01-29, 2021-01-30, 2021-01-31, 2021-03-10, 2021-03-16, 2021-05-24, 2021-06-01, 2021-07-24, 2021-09-19, 2021-10-08, 2021-10-28, 2021-10-29.

### 6.2.3 Geomagnetic Storms

Using an automated storm detection method [Bailey and Leonhardt, 2016], which aims to detect storms likely to cause geomagnetically induced currents, 16 storms were detected in the year 2021: 2021-01-05, 2021-01-11, 2021-01-25, **2021-03-20**, 2021-04-07, 2021-04-17, 2021-04-25, **2021-05-12**, 2021-05-17, 2021-05-20, 2021-05-26, 2021-06-02, 2021-06-07, 2021-05-15, **2021-11-03**, and 2021-11-30. The dates highlighted in bold were three of the five most active days during the year by maximum  $k_p$  value. Out of the 16 detections, five (2021-01-05, 2021-01-11, 2021-05-17, 2021-06-02, and 2021-06-07) were of SSC-like signals in the data that were not followed by geomagnetic storms. The technique makes use of a combination of NOAA real-time solar wind data along with geomagnetic recordings from the Observatory. An example of an automated storm detection using both sets of data is shown in Figure 6.3.

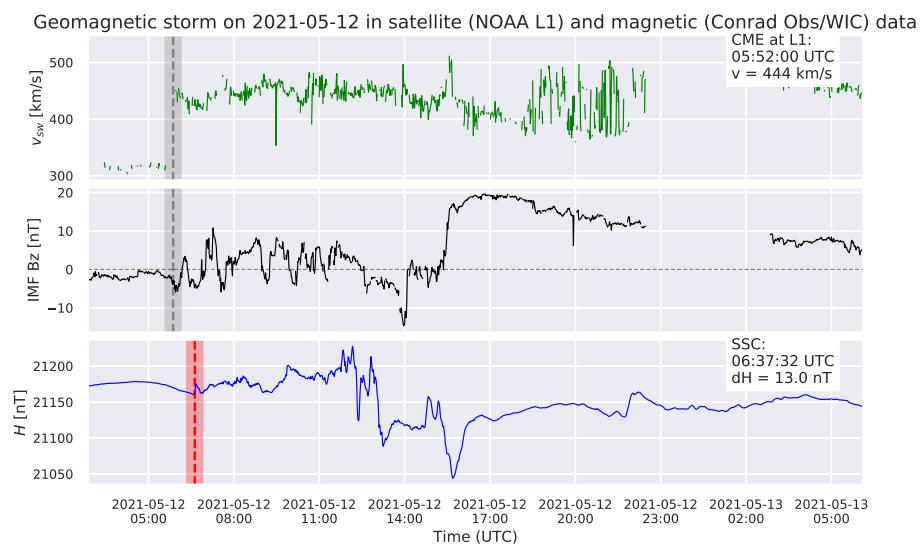

Figure 6.3 Most prominent geomagnetic storm in 2021. Shown are solar wind speed as determined at Lagrange point 1 (L1) by DSCOVR/ACE satellites and the horizontal component ( $H$ ) of the geomagnetic field. Denoted are the times when shock front of the coronal mass ejection (CME) passed the satellite and initiated the sudden storm commencement (SSC) on earth.
